## Solving Linear Equations with Variables on Both Sides Algebra 1

Often we will need to solve linear equations where the variable happens to be on both sides of the equality. The objective in solving these equations is the same as that of the simpler ones that we have seen - isolate the variable and solve for its value. The key is, as always, to manipulate the equation by doing the same thing to both of its sides. → Equality properties

*goal*  
★ Start by moving the smaller variable to the larger (so you don't have neg #'s)  
★ Use opposite operation b/c it's being moved to the opposite side

$$\begin{aligned}
 5x - 5 &= 2x + 13 \\
 -2x & \quad -2x \\
 \hline
 3x - 5 &= 13 \\
 +5 & \quad +5 \\
 \hline
 3x &= 18 \\
 \frac{3x}{3} &= \frac{18}{3} \quad x=6
 \end{aligned}$$

*Check*

$$\begin{aligned}
 5x - 5 &= 2x + 13 \\
 5(6) - 5 &= 2(6) + 13 \\
 30 - 5 &= 12 + 13 \\
 25 &= 25
 \end{aligned}$$

*PEMDAS*

As we see from this exercise, an equation truly works like a balancing scale. As long as we perform the same operation to both sides of the equation, like adding the same amount of weight to both sides of a scale, the equation remains valid - the scale remains balanced.

**Exercise #2:** Solve each of the following equations. Check and list the properties used.

(a)  $7x - 21 = x + 3$

$$\begin{aligned}
 -x & \quad -x \text{ sub of} \\
 \hline
 6x - 21 &= 3 \text{ Add Prop of} \\
 +21 & \quad +21 \text{ of} \\
 \hline
 6x &= 24 \text{ Div Prop of} \\
 \frac{6x}{6} &= \frac{24}{6} \\
 x &= 4
 \end{aligned}$$

(b)  $-4 + 3x = 6x + 32$

$$\begin{aligned}
 -3x & \quad -3x \text{ sub Prop of} \\
 \hline
 -4 - 3x &= 32 \text{ sub Prop of} \\
 -32 & \quad -32 \text{ of} \\
 \hline
 -36 &= 3x \text{ D.P.O.E} \\
 \frac{-36}{3} &= \frac{3x}{3} \\
 -12 &= x \quad x = -12
 \end{aligned}$$

(c)  $-2x - 18 = -4x - 6$

$$\begin{aligned}
 +4x & \quad +4x \text{ Add Prop of} \\
 \hline
 2x - 18 &= -6 \text{ Add Prop of} \\
 +18 & \quad +18 \text{ of} \\
 \hline
 2x &= 12 \text{ Div Prop of} \\
 \frac{2x}{2} &= \frac{12}{2} \text{ equal} \\
 x &= 6
 \end{aligned}$$

Sometimes we encounter problems where we need to combine like terms as well. It is advisable to combine like terms first.

**C** Combine like terms (same side, same operation) **M** over smaller variable to larger (Opp. side opp. operation) **S** Solve remaining equation

**Exercise #3:** Solve each of the following equations. Check and list the properties used.

(a)  $10 - 7x + x = 5x - 80 - 2x$

$$\begin{aligned}
 10 - 6x &= 3x - 80 \text{ Combine like terms} \\
 +6x & \quad +6x \text{ Add Prop of} \\
 \hline
 10 &= 9x - 80 \text{ Add Prop of} \\
 +80 & \quad +80 \text{ of} \\
 \hline
 90 &= 9x \text{ Div Prop of} \\
 \frac{90}{9} &= \frac{9x}{9} \\
 10 &= x \quad x = 10
 \end{aligned}$$

(b)  $10x - 3 - 8x = -x + 11 - 3x + 10$

$$\begin{aligned}
 2x - 3 &= -x + 21 \text{ combine like terms} \\
 +x & \quad +x \text{ A Prop of} \\
 \hline
 3x - 3 &= 21 \text{ Add Prop of} \\
 +3 & \quad +3 \text{ of} \\
 \hline
 3x &= 24 \text{ D.P.O.E} \\
 \frac{3x}{3} &= \frac{24}{3} \\
 x &= 4
 \end{aligned}$$

**Exercise #4:** Which of the following values of  $x$  satisfies the equation  $2x - 14 = 7x + 6$ ?

(1)  $x = -2$

(3)  $x = 5$

(2)  $x = 6$

(4)  $x = -4$

Do on calc  
1st to show

$$\begin{array}{r} -2x \quad -2x \\ -14 = 5x + 6 \\ -6 \quad -6 \\ \hline -20 = 5x \\ \frac{-20}{5} = \frac{5x}{5} \\ x = -4 \end{array}$$

It is important to continue our work with translating verbal phrases into equations. Some of these can also result in variables on both sides of the equation.

**Exercise #5:** Translate each of the following verbal sentences into an equation and then solve for the number described.

(a) Eight times a number is 36 more than twice the same number.

let  $x =$   
the #

$$\begin{array}{r} 8x = 2x + 36 \\ -2x \quad -2x \\ \hline 6x = 36 \\ \frac{6x}{6} = \frac{36}{6} \\ x = 6 \end{array}$$

the #  
is 6.

(b) If three times a number is increased by 24, the result is six times the same number.

let  $x =$   
the #

$$\begin{array}{r} 3x + 24 = 6x \\ -3x \quad -3x \\ \hline 24 = 3x \\ \frac{24}{3} = \frac{3x}{3} \\ 8 = x \end{array}$$

switch order

the #  
is 8.

(c) If three times a number is increased by 22, the result is 14 less than seven times the same number.

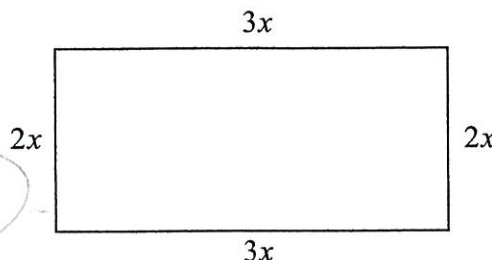

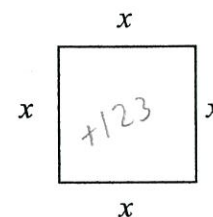

let  $x =$   
the #

$$\begin{array}{r} 3x + 22 = 7x - 14 \\ -3x \quad -3x \\ \hline 22 = 4x - 14 \\ +14 \quad +14 \\ \hline 36 = 4x \\ \frac{36}{4} = \frac{4x}{4} \\ 9 = x \end{array}$$

the # is 9

**Exercise #6:** A square and a rectangle are shown below with side lengths in terms of  $x$ . The perimeter of the rectangle is 123 more than the perimeter of the square. Find the value of  $x$ .

$$3x + 3x + 2x + 2x = x + x + x + x + 123$$

\* If the rectangle is heavier add the # to the square instead so they will be equal

$$\begin{array}{r} 10x = 4x + 123 \\ -4x \quad -4x \\ \hline 6x = 123 \\ \frac{6x}{6} = \frac{123}{6} \\ x = 20\frac{1}{2} \end{array}$$

$x = 20\frac{1}{2}$

ADD all the sides
